

# LY $\alpha$ ABSORBERS DO/NOT CO-ROTATE WITH GALAXY DISKS

DAVID M. FRENCH, BART P. WAKKER

Department of Astronomy, University of Wisconsin, Madison, WI 53706, USA

*Draft version February 16, 2018*

## ABSTRACT

We present results of a study comparing the relative velocity of Ly $\alpha$  absorbers to the rotation direction and velocity of nearby galaxy disks. We find...

*Subject headings:* galaxies:intergalactic medium, galaxies:evolution, galaxies:halos, quasars: absorption lines

## 1. INTRODUCTION

Galaxy rotation curves have been observed to extend at constant velocity out to... (cite...). It becomes increasingly difficult to measure gas rotation much farther from this however as the density rapidly decreases. Within this region the galaxy disks transition into circumgalactic medium (CGM), and eventually the CGM merges with the intergalactic medium (IGM). At what point, however, does the surrounding medium cease to circulate with the galaxy? Stewart et al. (2011) suggests through (HYDRO?) simulations that the bulk CGM kinematics out to (WHAT DISTANCE) may circulate, and that absorption in intervening QSO sightlines should be able to accurately capture this rotation signature.

There have been several studies with a sample size of 1 or a few aiming to compare the kinematics of the galaxy disk to absorption detected in it's CGM halo (e.g., Wakker & Savage 2009, Bowen et al. 2016, **MORE**). With these individual results we may be missing the forest for the sake of the individual trees. There has yet to be a more systematic search for observational evidence that the CGM is kinematically associated with galaxies in general.

Numerous studies have shown a correlation between equivalent width and decreasing velocity difference between galaxies and IGM absorbers (e.g., French & Wakker 2017, **MORE**).

## 2. DATA AND ANALYSIS

### 2.1. SALT Data

Our sample contains 12 galaxies observed with the Southern African Large Telescope (SALT) Robert Stobie Spectrograph (RSS) in longslit mode. These 12 were selected from a larger pool of 48 submitted targets by the SALT observing queue. These 48 possible targets were chosen for their proximity to background QSOs whose spectra contained promising Ly $\alpha$  lines. Finally, we only included galaxies with  $z \leq 0.33$  ( $cz \leq 10,000$  km s<sup>-1</sup>), angular sizes less than 6' to ensure easy sky subtraction, and surface brightnesses sufficient to keep exposure times below 1300s. Table 2 summarizes these observations. Data was taken for 2 additional galaxies, NGC3640 and NGC2962, but proved unusable due to issues with spectral identification and low signal to noise (respectively).

All SALT galaxy spectra were reduced and extracted using the standard PySALT reduction package (**CITATION**), which includes procedures to prepare the

data, correct for gain, cross-talk, bias, and overscan, and finally mosaic the images from different extensions. Next, we rectify the images with wavelength solutions found via Ne and Ar arc lamp spectra line identification. Finally, we perform a basic sky subtraction using an off-sky portion of the image, and extract 5-10 pixel wide 1-D strips from the reduced 2-D spectrum.

For each 1-D spectrum, we identify the H $\alpha$  emission lines and perform a non-linear least-squares Voigt profile fit using the Python package LMFIT<sup>1</sup>. The line centroid and 1 $\sigma$  standard errors are returned, and these fits are then shifted to rest-velocity based on the galaxy systemic redshift and heliocentric velocity corrections are calculated with the IRAF rvcorrect procedure. The final rotation velocity is calculated by then applying the inclination correction,  $v_{rot,i} = v/\sin(i)$ . Final errors are calculated as

$$\sigma^2 = \left(\frac{\partial v_{rot}}{\partial \lambda_{obs}}\right)^2 (\Delta \lambda_{obs})^2 + \left(\frac{\partial v_{rot}}{\partial v_{sys}}\right)^2 (\Delta v_{sys})^2 + \left(\frac{\partial v_{rot}}{\partial i}\right)^2 (\Delta i)^2, \quad (1)$$

where  $\Delta \lambda_{obs}$ ,  $\Delta v_{sys}$ , and  $\Delta i$  are the errors in observed line center, galaxy redshift, and inclination, respectively. We determine the inclination error by calculate the standard deviation of all axis ratio values available for each galaxy in NED. The final physical scale is calculated using the SALT image scale of 0.1267 arcsec/pixel, multiplied by the 4-pixel spatial binning, and converted to physical units using a redshift-independent distance if available, and a Hubble flow estimate if not. We adopt a Hubble constant of  $H_0 = 71$  km s<sup>-1</sup>Mpc<sup>-1</sup> throughout.

Finally, we calculate our approaching and receding velocities via a weighted mean of the outer 1/2 of each rotation curve, with errors calculated as weighted standard errors in the mean. Our final redshifts are calculated by forcing symmetric rotation, such that the outer 1/2 average velocity for each side matches. See Figure ?? for an example.

## 2.2. Ancillary Data

## 2.3. Galaxy Data

## 2.4. Spectra

## 3. RESULTS

To facilitate this decision, we calculate the likelihood,  $\mathcal{L}$ , of every possible galaxy-absorber pairing as follows:

$$\mathcal{L} = A e^{-\left(\frac{\rho}{R_{eff}}\right)^2} e^{-\left(\frac{\Delta v}{200}\right)^2}. \quad (2)$$

Here  $\rho$  is the physical impact parameter,  $\Delta v$  the velocity difference between the absorber and the galaxy ( $\Delta v = v_{galaxy} - v_{absorber}$ ), and  $A$  is a factor included to increase the likelihood in the case that  $\rho \leq R_{eff}$  (in which case

$A = 2$ , otherwise  $A = 1$ ).

## 4. SUMMARY

- First result

This research has made use of the NASA/IPAC Extragalactic Database (NED) which is operated by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration. Based on observations with the NASA/ESA *Hubble Space Telescope*, obtained at the Space Telescope Science Institute (STScI), which is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS 5-26555. **SALT ACKNOWLEDGEMENT.** Spectra were retrieved from the Barbara A. Mikulski Archive for Space Telescopes (MAST) at STScI.
