Draft version March 2, 2018

ABSTRACT

We present results of a study comparing the relative velocity of Ly α absorbers to the rotation direction and velocity of nearby galaxy disks. We find...

Subject headings: galaxies:intergalactic medium, galaxies:evolution, galaxies:halos, quasars: absorption lines

1. INTRODUCTION

Galaxy rotation curves have been observed to extend at constant velocity out to... (cite...). It becomes increasingly difficult to measure gas rotation much farther from this however as the density rapidly decreases. Within this region the galaxy disks transition into circumgalactic medium (CGM), and eventually the CGM merges with the intergalactic medium (IGM). At what point, however, does the surrounding medium cease to circulate with the galaxy? Stewart et al. (2011) suggests through (HYDRO?) simulations that the bulk CGM kinematics out to (WHAT DISTANCE) may circulate, and that absorption in intervening QSO sightlines should be able to accurately capture this rotation signature.

Côté et al. 2005 probed the halos of nine galaxies using *HST* observed background QSOs, finding large warps would be needed to explain the velocity of *H i* absorbers by an extended rotating disk.

There have been several studies with a sample size of one or a few aiming to compare the kinematics of the galaxy disk to absorption detected in it's CGM halo (e.g., Côté et al. 2005; Wakker & Savage 2009; Bowen et al. 2016; **MORE**). With these individual results we may be missing the forest for the sake of the individual trees. There has yet to be a more systematic search for observational evidence that the CGM is kinematically associated with galaxies in general.

Numerous studies have shown a correlation between equivalent width and decreasing velocity difference between galaxies and IGM absorbers (e.g., French & Wakker 2017, **MORE**).

To make progress here, we have obtained rotation curves for 12 nearby spiral galaxies which are located within 500 kpc of a background QSO observed by the Cosmic Origins Spectrograph (COS) on *HST*.

2. DATA AND ANALYSIS

2.1. SALT Data

Our sample contains 12 galaxies observed with the Southern African Large Telescope (SALT) Robert Stobie Spectrograph (RSS) in longslit mode. These 12 were selected from a larger pool of 48 submitted targets by the SALT observing queue. These 48 possible targets were chosen for their proximity to background QSOs whose spectra contained promising Ly α lines. Finally, we only included galaxies with $z \leq 0.33$ ($cz \leq 10,000$ km s⁻¹), angular sizes less than 6' to ensure easy sky subtraction, and surface brightnesses sufficient to keep exposure times

below ~ 1300 s. Table 2 summarizes these observations. Data was taken for 2 additional galaxies, NGC3640 and NGC2962, but proved unusable due to issues with spectral identification and low signal to noise (respectively).

All SALT galaxy spectra were reduced and extracted using the standard PySALT reduction package (**CITATION**), which includes procedures to prepare the data, correct for gain, cross-talk, bias, and overscan, and finally mosaic the images from different extensions. Next, we rectify the images with wavelength solutions found via Ne and Ar arc lamp spectra line identification. Finally, we perform a basic sky subtraction using an off-sky portion of the image, and extract 5-10 pixel wide 1-D strips from the reduced 2-D spectrum.

For each 1-D spectrum, we identify the H α emission lines and perform a non-linear least-squares Voigt profile fit using the Python package LMFIT¹. The line centroid and 1σ standard errors are returned, and these fits are then shifted to rest-velocity based on the galaxy systemic redshift and heliocentric velocity corrections are calculated with the IRAF rvcorrect procedure. The final rotation velocity is calculated by then applying the inclination correction, $v_{rot} = v/\sin(i)$. Final errors are calculated as

$$\sigma^2 = \left(\frac{\partial v_{rot}}{\partial \lambda_{obs}}\right)^2 (\Delta \lambda_{obs})^2 + \left(\frac{\partial v_{rot}}{\partial v_{sys}}\right)^2 (\Delta v_{sys})^2 + \left(\frac{\partial v_{rot}}{\partial i}\right)^2 (\Delta i)^2, \quad (1)$$

where $\Delta \lambda_{obs}$, Δv_{sys} , and Δi are the errors in observed line center, galaxy redshift, and inclination, respectively. We determine the inclination error by calculate the standard deviation of all axis ratio values available for each galaxy in NED. The final physical scale is calculated using the SALT image scale of 0.1267 arcsec/pixel, multiplied by the 4-pixel spatial binning, and converted to physical units using a redshift-independent distance if available, and a Hubble flow estimate if not. We adopt a Hubble constant of $H_0 = 71$ km s⁻¹Mpc⁻¹ throughout.

Finally, we calculate our approaching and receding velocities via a weighted mean of the outer 1/2 of each rotation curve, with errors calculated as weighted standard errors in the mean. Our final redshifts are calculated by

Table 1

COS targets in this sample. *Total exposure time and S/N ratio is given for multi-orbit exposures.

forcing symmetric rotation, such that the outer 1/2 average velocity for each side matches. See Figure ?? for an example.

2.2. COS Spectra

The Barbara A. Mikulski Archive for Space Telescopes (MAST) archives yield 19 QSO targets observed by COS which lie within 500 kpc of our SALT galaxies. These targets vary widely in signal-to-noise from approximately 5 to 100 due to our choosing them based only on their proximity to galaxies with known rotation. The reduction procedure for these spectra follow those described by French & Wakker 2017 and Wakker et al. (2015). In short, spectra are processed with CALCOS vXXXX? and combined via the method of Wakker et al. (2015), which helps corrects the COS wavelength scale misalignments produced by CALCOS. Multiple exposures are combined via alignment with Galactic 21cm absorption spectra and summing total counts per pixel before converting to flux. The COS instrument is described in detail by Green et al. (2012).

3. SALT GALAXIES

3.1. CGCG039-137

CGCG039-137 is an isolated Scd type galaxy with a measured systemic velocity of $6918 \pm 24 \text{ km s}^{-1}$ and inclination of 63° . There are two associated sightlines: RXJ1121.2+0326 at an impact parameter of 99 kpc and azimuth angle of 71° on the receding side, and SDSSJ112224.10+031802.0 at 491 kpc and 24° on the approaching side. Ly α absorption is detected in both sightlines within 400 km s^{-1} of CGCG039-137.

Towards RXJ1121.2+0326 we detect Ly α at 6975 km s^{-1} , which, at $\Delta v = 57 \text{ km s}^{-1}$, lies well within the range of projected velocities consistent with co-rotation. The absorber detected toward SDSSJ112224.10+031802.0 occurs at a more distant 6606 km s^{-1} ($\Delta v = -312 \text{ km s}^{-1}$). Although this absorber has the correct sign for co-rotation (blue-ward on the approaching side of the disk), the large velocity difference

and impact parameter make it unlikely that this absorption can be linked to coherent halo rotation.

3.2. ESO343-G014

ESO343-G014 is an edge on spiral galaxy with a measured systemic velocity of $9138.9 \pm 31.7 \text{ km s}^{-1}$. It has a smaller neighboring galaxy, 2MASXJ21372816-3824412, located north of it's major axis at a projected distance of 216 kpc and velocity of 9129. The nearest sightline is towards RBS1768 at an impact parameter of 466kpc and 74° azimuth angle on the approaching side. We detect 3 Ly α absorption lines within 300 km s^{-1} of ESO343-G014 (at 9308, 9360, and 9434 km s^{-1}). All of these are anti-aligned with the rotation of ESO343-G014, but unfortunately the presence of 2MASXJ21372816-3824412 makes it difficult to attribute this gas solely to ESO343-G014. Additionally, this gas could be attributed to either the approaching or receding side of the disk due to the large impact parameter and high azimuth angle of the sightline.

3.3. IC5325

IC5325 is a face-on SAB(rs)bc type galaxy with a measured velocity of $1511.9 \pm 8.4 \text{ km s}^{-1}$. It's inclination is just high enough (25°) to obtain a reasonable rotation curve. The closest neighboring galaxy is ESO347-G020 to the Southeast at 306 kpc and a heliocentric velocity of 1745 km s^{-1} . Three other much smaller galaxies are also located $\sim 450 \text{ kpc}$ to the Southwest. We detect Ly α absorption at 1598 km s^{-1} , $\Delta v = 86 \text{ km s}^{-1}$ in the spectrum towards RBS2000 at an impact parameter of 314 kpc and azimuth angle of 64° on the approaching side. While this velocity is anti-aligned with the rotation the disk gas, the low inclination angle of IC5325 leads to a highly uncertain position angle. Without additional observations, we cannot say for certain if the location of RBS2000 actually lies on the approaching or receding side. This position angle uncertainty also means our SALT rotation curve is a lower limit on the true rotation velocity of IC5325.

3.4. MCG-03-58-009

MCG-03-58-009 is a massive and very isolated Sc type galaxy at a measured velocity of $9015 \pm 19 \text{ km s}^{-1}$ and inclination angle of 49° . A weak Ly α absorber is detected at 9029 km s^{-1} towards MRC2251-178, which lies 355 kpc away at an azimuth angle of 71° on the receding side. Although this absorber matches the velocity direction expected for co-rotation, the velocity difference ($\Delta v = 14 \text{ km s}^{-1}$) is within the systemic velocity uncertainty. The relative weakness of this absorber ($\text{EW} = 62 \pm 4 \text{ m\AA}$) is somewhat surprising given it's proximity (just outside of $1 R_{\text{vir}}$) to a massive galaxy. If this is representative of an isolated system such as MCG-03-58-009, then we should expect the halo rotational velocity to approach systemic by $1 R_{\text{vir}}$.

3.5. NGC1566

NGC1566 is well sampled (5 nearby QSO sightlines), but unfortunately also part of a complex environment of neighboring galaxies. We detect Ly α in all 5 of these sightlines. The farthest three, HE0439-5254, RBS567, and HE0435-5304, are clustered close together to the

Figure 1. Rotation curve of NGC3633. The solid green line indicates the weighted mean velocity over the corresponding x-axis region, and the shaded green indicates the 1σ error in the mean.

Table 2

SALT targeted galaxies. Columns are as follows: 1) the galaxy name, 2), 3) R.A., Dec. in J2000, 4) galaxy systemic velocity, 5) morphological type (RC3), 6) RSS grating used, 7) approaching side velocity, 8) receding side velocity, 9) observation date, 10) exposure time, and 11) S/N of the H α or Ca H&K lines.

northeast of NGC1566 at $\gtrsim 395$ kpc and azimuth angles of $\sim 60^\circ$.

HE0429-5343 is in the same direction and azimuth angle but closer at $\rho = 256$ kpc, and

1H0419-577 is located to the south at 303 kpc and just east of the receding side of the major axis at an azimuth angle of 10° . We detect Ly α at 1071, 1123, 1188, 1264, and 2020 km s^{-1} , all of which are the wrong sign for co-rotation or distant in velocity. This sightline is actually closer to a small group of galaxies including NGC1549, NGC1546 and NGC1536, all with systemic velocities near 1200 km s^{-1} . We expect the lines at 1071, 1123, 1188, 1264 km s^{-1} to be associated with this group rather than with NGC1566.

3.6. NGC3513

Systemic velocity as published: 1194 Velocity as measured: 1203.7 ± 12.0 Rotation velocity (inc corrected) 20 ± 22 km s^{-1} Rotation velocity (observed) 11 ± 9 km s^{-1} Inclination: 30 Adjusted Inc: 30 Morphology: SB(s)c.HII $L_* = 0.49$

One sightline:

H1101-232 at 60 kpc, 67deg az:
1182 Lya ($dv = -22$ km s^{-1} on pos side)

3.7. NGC3633

Several locations show two velocities for emission. We have combined these into a single velocity measurement via a weighted average. We measure a redshift for this galaxy of $cz = 2597.6 \pm 2.4$ km s^{-1} .

We measure a line-of-sight rotation velocity for NGC3633 of $v_{\text{rot}} = 139 \pm 3.3$, -160 ± 5.7 , km s^{-1} .

Systemic velocity as published: 2600 Velocity as measured: 2587.2 ± 6.6 Rotation velocity (inc corrected) 157 ± 11 km s^{-1} Rotation velocity (observed) 149 ± 6 km s^{-1} Inclination: 69 Adjusted Inc: 72 Morphology: SAa $L_* = 0.88$

Three sightlines:

SDSSJ112005.00+041323.0 at 468 kpc, 78deg az:
2285 Lya ($dv = -302$ km s^{-1} on neg side) 2578 Lya ($dv =$

-9 km s^{-1} on neg side)

RXJ1121.2+0326 at 184 kpc, 58deg az:

2605 Lya ($dv = 18$ km s^{-1} on neg side)

SDSSJ112224.10+031802.0 at 413 kpc, 50deg az:

Nothing

3.8. NGC4536

The data on the receding side of NGC4536 is very messy, and may include contamination from background sources.

Systemic velocity as published: 1808 Velocity as measured: 1866.9 ± 32.9 Rotation velocity (inc corrected) 139 ± 37 km s^{-1} Rotation velocity (observed) 129 ± 32 km s^{-1} Inclination: 59 Adjusted Inc: 61 Morphology: SAB(rs)bc $L_* = 2.0$

Three sightlines:

3C273.0 at 349 kpc, 11deg az:

1580 Lya ($dv = -287$ km s^{-1} on pos side) 2156 Lya ($dv = 289$ km s^{-1} on pos side) 2267 Lya ($dv = 400$ km s^{-1} on pos side)

HE1228+0131 at 338 kpc, 51deg az:

1495 Lya ($dv = -372$ km s^{-1} on pos side) 1571 Lya ($dv = -296$ km s^{-1} on pos side) 1686 Lya ($dv = -181$ km s^{-1} on pos side) 1721 Lya ($dv = -146$ km s^{-1} on pos side) 1854 Lya ($dv = -13$ km s^{-1} on pos side) 2311 Lya ($dv = 444$ km s^{-1} on pos side)

SDSSJ123748.99+012607.0 at 294 kpc, 37deg az:
not finished

3.9. NGC4939

Systemic velocity as published: 3110 Velocity as measured: 3092.8 ± 33 Rotation velocity (inc corrected) 275 ± 49 km s^{-1} Rotation velocity (observed) 204 ± 25 km s^{-1} Inclination: 46 Adjusted Inc: 48 Morphology: SA(s)bc $L_* = 5.5$

One sightline:

PG1302-102 at 254 kpc, 61deg az:

3448 Lya ($dv = 355$ km s^{-1} on neg side)

3.10. NGC5364

Systemic velocity as published: 1241 Velocity as measured: 1238.0 ± 16.9 Rotation velocity (inc corrected) $155 \pm 27 \text{ km s}^{-1}$ Rotation velocity (observed) $130 \pm 13 \text{ km s}^{-1}$ Inclination: 55 Adjusted Inc: 57 Morphology: SA(rs)bc $L_* = 1.9$

Two sightline:
SDSSJ135309.50+033328.0 at 519 kpc, 21deg az:
not finished

SDSSJ135726.27+043541.4 at 165 kpc, 84deg az:
1124 Lya (dv = -114 km s^{-1} on pos? side) 1296 Lya (dv = 58 km s^{-1} on pos? side)

3.11. NGC5786

Systemic velocity as published: 2998 Velocity as measured: 2974.6 ± 21.5 Rotation velocity (inc corrected) $172 \pm 28 \text{ km s}^{-1}$ Rotation velocity (observed) $156 \pm 19 \text{ km s}^{-1}$ Inclination: 63 Adjusted Inc: 65 Morphology: (R'2)SAB(s)bc $L_* = 25$

One sightline:
QSO1500-4140 at 453 kpc, 1deg az:
3141 Lya (dv = 166 km s^{-1} on pos side)

3.12. UGC09760

Systemic velocity as published: 2023 Velocity as measured: 2093.7 ± 15.5 Rotation velocity (inc corrected) $46 \pm 16 \text{ km s}^{-1}$ Rotation velocity (observed) $46 \pm 12 \text{ km s}^{-1}$ Inclination: 85 Adjusted Inc: 90 Morphology: Sd $L_* = 0.17$

Two sightlines:
SDSSJ151237.15+012846.0 at 123 kpc, 90deg az:
2051 Lya (dv = -43 km s^{-1} on minor axis. Looks neg side, but extremely close)

3.13. Ancillary Data

To increase our sample size we have also searched the literature for galaxies with published rotation curves and orientations. Unfortunately, while the rotation velocity is available for thousands of galaxies, only a handful also include the *orientation* of the rotation on the sky.

4. HALO ROTATION MODEL

In order to better understand how QSO sightlines probe intervening velocity structure we have developed a simple halo gas rotation model. This model is seeded by an observed rotation curve (or whatever rotation curve-like data suits one's fancy). This input curve is then interpolated and extended out to $2R_{vir}$ based on the average velocity of the outer 1/2 radius. Next, we project this interpolated rotation curve onto a plane oriented to a faux QSO sightline identically to the input galaxy-QSO pair orientation. By stacking multiple rotation-planes in the galaxy z-axis direction, we then create a simple cylindrical rotating halo model. Finally, each rotation-plane in the stack is projected onto the faux sightline. The result is a function representing the rotation velocity encountered by the sightline as a function of velocity (or distance) along it.

For each galaxy-QSO pair we created 3 rotation models: 1) a purely cylindrical halo extending $1R_{vir}$ in height and $2R_{vir}$ in radius, 2) a spherical halo extending $2R_{vir}$ in radius, and 3) a cylindrical model extending $1R_{vir}$ in height and $2R_{vir}$ in radius with rotation velocities which smoothly decline to systemic towards these boundaries.

5. DISCUSSION

6. SUMMARY

- First result

This research has made use of the NASA/IPAC Extragalactic Database (NED) which is operated by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration. Based on observations with the NASA/ESA *Hubble Space Telescope*, obtained at the Space Telescope Science Institute (STScI), which is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS 5-26555. **SALT ACKNOWLEDGEMENT.** Spectra were retrieved from the Barbara A. Mikulski Archive for Space Telescopes (MAST) at STScI. Over the course of this study, D.M.F. and B.P.W. were supported by grant AST-1108913, awarded by the US National Science Foundation, and by NASA grants *HST*-AR-12842.01-A, *HST*-AR-13893.01-A, and *HST*-GO-14240 (STScI).

HST (COS)

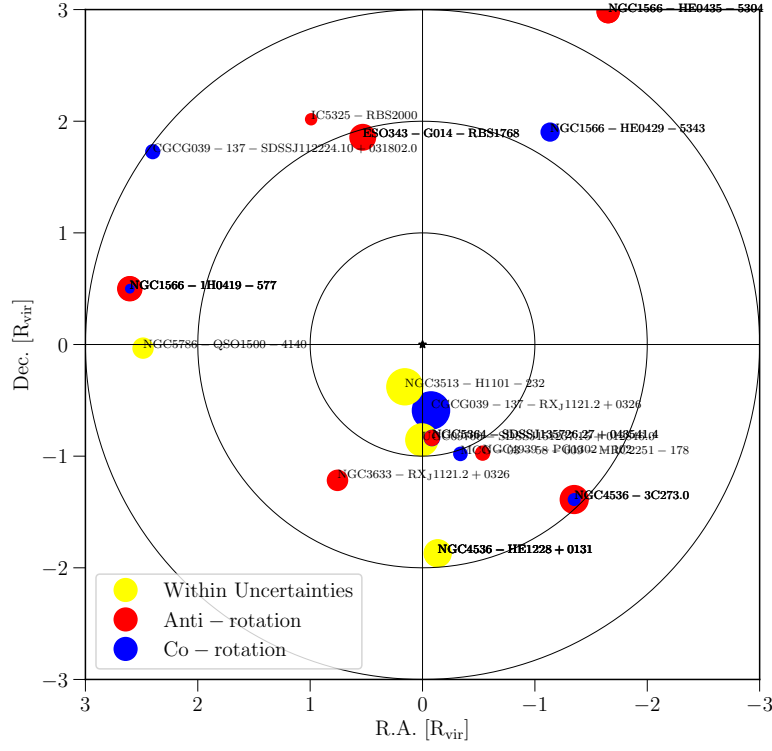

Figure 2. A map of the locations of each absorber normalized with respect to the galaxy virial radius. Concentric rings indicate distances of 1, 2 and 3 R_{vir} . All galaxies are rotated to PA = 90, such that their major axis' are horizontal. The color of the points indicates their line-of-sight velocity compared to that of the rotation of the nearby galaxy. Blue indicates co-rotation, red indicates anti-rotation, and yellow indicates cases where either is possible due to a combination of orientation and velocity uncertainties. The size of each point is scaled to reflect the EW of the absorber.
